MEMORANDUM REPORT ON

WCTSE/NJG/wg

Date 5 July 1951

SUBJECT:

Phase II Tests on the MO-120 Airplane, USAF No. 48 330

OFFICE.

WCTSE

SERIAL No. WOT-2344

A. PURPOSE:

1. To report the results of Phase II flight tests conducted on the MC-120 airpiane, USAF No. 48-330.

B. FACTUAL DATA:

2. Introduction:

Flight tests were conducted in accordance with AMC Hq Office Instruction No. 30-4, dated 25 May 1950. To accomplish these tests 19 test flights, totaling 39.1 hours, were flown at Wright-Patterson Air Force Base by WADC personnel from 18 February 1951 to 6 April 1951. In addition to the above flights, the airplane was flown to Eglin AFB and then to Randolph AFB for display purposes, which required approximately 15 hours of flying time.

3. Description of Aircraft

a. The Fair-child XC-120 airplane is a twin-boom, high wing, all metal cargo type aircraft powered by two Pratt and Whitney R-4360-20W engines, supercharged by single stage, variable speed high blowers. The supercharged engines drive four bladed Hamilton Standard hydromatic full feathering, constant ageed, reversible pitch propellers. The propeller blade drawing number is A2H1713-26. The blades were set for a minimum angle of 18°, a maximum angle of 83°, and a negative setting of 21° for reversible pitch operation. The XC-12C is a modification of the C-119B aircraft. Dimensions, design limits, photographs, and general information appear in Appendix II of this report. The cargo section (pack) can be detached from the aircraft coarrier which is designed to have satisfactory flying characteristics with or without the pack. The quadricycle landing gear consists of four retractable dual wheel units; two in each nacelle,

b. All equipment, with the exception of the hydraulic brake system and the hydromatic propeliers, is electrically operated. The elevator and rudders are equipped with spring loaded tabs in addition to

the trim tabs. Both ailerons are equipped with mechanical balance tabs. The alleron and rudder trim tabs are electrically operated, while the elevator trim tab is manually operated. The airplane is equipped with electrically controlled automatic cowl flaps, oil cooler flaps, and carburetor air heat, but manual selection is also provided. During the Phase II tests, the automatic feature for the cowl flaps and carburetor air heat were deleted.

4. Test Configuration:

The airplane was weighed with a full fuel load of 2798 gallons and full oil tanks (120 gallons), and the pack attached to the carrier and then reweighed with the pack detached. The airplane was flown at a take-off gross weight of 64,000 pounds with pack on and 55,000 pounds with pack off at various CG's. With pack on and full fuel, oil, test equipment of approximately 2500 pounds, and a crew of five, the airplane weighed approximately 63,000 pounds. An additional 1000 pounds of ballast was needed to load the airplane to its design weight of 64,000 pounds. However, this was not a sufficient amount of ballast to obtain and maintain a forward CG of 20% M.A.C.; therefore, it was necessary to reduce the fuel load so additional ballast could be placed in the nose to obtain the forward CG and still not exceed the design weight limits.

5. Cockpit Layout:

In general, the cockpit was comfortable and well arranged for pilot conveniences. Entering and leaving the cockpit with pack on was accomplished through the pack and up a ladder to the crew compartment. With pack off, entrance was gained by means of a collapsible, portable ladder to the crew compartment. The ladder may be extended and retracted from crew compartment hatch to the ground, or from the ground to the carrier.

- b. The control column strikes the pilot's and copilot's seat when the seats are in the full forward position. Movement of the seat one inch to the rear would relieve this condition. The control wheel was mounted too low and interferred with the average pilot's knees.
- c. All coskpit controls were placed in such a manner as to be readily available to the pilot; however, on the overhead panel in the emergeous section, the fire warning lights, engine fire extinguisher, fuel shut off, and heater fire extinguisher switches are not sufficiently well segregated as to make the group or individual switches readily distinguishable in an emergency. Also, on the overhead panel are three important switches (hydraulic brake pump, main inverter, auto pilot inverter) in the same proximity that can easily be knocked to the "off" position when the copilot (with back pack parachute) leaves his seat. One or more of these switches were knocked to the "off" position several times during the test program in the above manner.
- d. The master battery and engine switch handles are designed in such a manner that they give a false indication as to the position of the switch. The impression is given that the index of the handle is 180° opposite to its actual position. When grasping the handle, the index end is completely covered, concealing the switch position. Local remedy was made by painting an

RESTRICTED

Memorandum Report No. WCT-2344

arrow on the switch handle proper, indicating the index end. The detent for the master battery switch is such that the switch isn't always placed in the "on" position for starting the engines in that the detent is not positive enough to insure correct seating.

- e. With shoulder harness in the locked position, it is impossible for the copilot to reach the landing gear control switch without unlocking the harness release or maintaining a loose shoulder harness. Both pilot's and copilot's shoulder harness inertia release malfunctioned at critical times. Local reworking of the unlocking mechanism enabled a normal release to be made on subsequent flights.
- f. Both pilot's and copilot's brake pedals are installed on the same plane as the rudder stirrups. It is impossible to tell if the foot is centered on the brake pedal or partially on the brake and stirrup, with the rudder stirrup and brake pedal installed on the same plane. If the pilot's foot is offset on the brake pedal it is possible to apply force to the rudder stirrup but with no resulting brake action.

6. Taxiing and Ground Handling:

- a. The quadricycle type gear, with the long stroke auxiliary gear oleo struts and suspension, lends itself to a smooth, soft ride during taxing. Although braking action causes the aircraft to bob, this is not considered objectionable as its magnitude is limited and dampens out readily. Direction is readily controlled, during all ground maneuvers, by application of brakes, rudders, or engines or combinations of all three. Although the aircraft turning radius is somewhat larger than most aircraft of this size, the turning radius is not excessive and allows ready movement on the ramp. In general, the ground handling characteristics were considered superior or equal to most nonsteerable tricycle geared aircraft; however, the design of the auxiliary nose gear does not permit the aircraft to be backed up by use of reverse thrust. This hinders the utility of the aircraft somewhat in ground maneuvering.
- b. The method of ground towing is somewhat more complicated and restricted than conventional or tricycle geared aircraft. Conventional ground handling equipment must be supplemented with special equipment, as shown on Page 15, Appendix II, to keep both wheels tracking parallel to each other when backing up and also to maintain directional control. This necessitates carrying the extra equipment in the aircraft, if landings are to be made at bases other than the home base.
 - c. Visibility from the cockpit is good during ground movement.

7. Take Off and Initial Climb:

a. During performance take offs at 64,000 pounds pack on and full power applied before brake release, the aircraft had a definite tendency to turn to the left shortly after brake release, although full right rudder was applied. This necessitated asymmetric power to insure adequate directional control. At about 35 knots (40 mph) full power could be applied to both engines

with no loss of directional control. Directional control was adequate throughout the take off run in the pack off configuration.

- b. During short field take offs, care must be exercised to avoid contacting the pack skid (with pack on or rudders with pack off) with the runway. It was possible to do this in either configuration even at forward CG's; thus, maximum $C_{\rm T}$ take offs were avoided.
- c. Visibility forward, in all configurations, was excellent at all times during normal take-offs and initial climb.
- d. The extended landing gear imposed a high degree of drag; therefore, it was advisable to accomplish the retraction as soon as practicable after take off. Several times during the test program the gears failed to retract simultaneously. When this occurred, there was a slight yaw in the direction of the extended gear. The pilot was always cognizant if one gear failed to retract because of the resulting yaw and drag.
- e. When the landing gear starts to retract there is a slight decederation as the auxiliary landing gear fairing passes through the vertical plane where it offers a flap plate area 90 degrees to the slip stream. Early tests were flown with a time delay lag that momentarily halted the auxiliary gear in the vertical plane during the retraction cycle. This created a very undesirable drag; however, this condition was later eliminated by timing the auxiliary gear retraction so that immediate retraction started when the landing gear was placed in the "up" position.
- f. All take-offs were made with wide-open cowl flaps and oil shutters set to 30° open. Take-offs were conducted with the wing flaps in the take-off position (15°) and in the "up" position. It was impossible to obtain military power in a static position because of the propeller low pitch setting of 18°; however, military power was developed shortly after brake release and maintained throughout the take-off and climb out. To reduce variables to a minimum, maximum power was applied before brake release and the gear was left down until above the 50-foot obstacle. The take-offs were recorded photographically and the data plotted in Appendix III. The data, corrected to standard conditions and 3000 bhp, are tabulated in the following table:

RESTRICTED

8. Climb Performance:

a. Sawtooth climbs were flown with pack on and off in order to check the manufacturer's estimated best rate of climb. The data compare favorably with the contractor's estimated data. The sawtooth climbs were flown with wide open cowl flaps, fixed oil cooler shutters, and normal rated power. The data have been corrected to standard conditions and are plotted in Figures 2 and 3, Appendix I.

b. Two check climbs, pack on and off, were made to service ceiling using wide open cowl flaps, fixed oil shutters, and normal rated power. Climb speed was determined from the sawtooth climbs and from the contractor's estimated data. All climb data have been corrected to standard atmospheric conditions and are plotted in Figure 1, Appendix 1. The climb performance at 2550 rpm is summarized in the following table:

		R/C I	T/MIN.	T/C MIN.						
ALTITUDE FT.	BHP/ENG	PACK ON	PACK OFF	PACK ON	PACK OFF					
s. L.	2 560	700	1060	0	0					
6,000	2630	780	1140	8.0	5.5					
10,000	2470	640	1030	13.5	9.5					
15,000	2340	480	900	22.0	14.5					
20,000	2120	260	660	3 6	20.5					
22,800	1960	100 S.C.	490	51.0	25.5					
28,000	1610	69 예 입고	100 S.C.	Ma (20 M2)	45.5					

c. Single engine climbs, clean configuration, pack on and off, were conducted with the left propeller feathered and all cooling devices closed. The right engine was operated at military power with the cowl flaps wide open and the oil cooler shutters fixed at 35° open. The contractor's best single engine climb speeds were used for the single engine climbs. The absolute (zero rate of climb) single engine ceiling, for pack on and at a gross weight of 63,000 pounds, was 3300 ft. The estimated maximum rate of climb is 50 ft. per minute at 2,000 ft. The service ceiling for "pack off" and at a gross weight of 54,500 pounds, was 6800 feet. All data have been corrected to standard conditions and are plotted in Figure 1, Appendix I.

9. Level Flight Performance:

a. Speed versus power data were obtained at 10,000 and 18,000 feet, pack on and off. The speed power at 10,000 feet, pack on, was flown at a constant cowl flap setting of 2.0 inches open and oil shutters set to 30 degrees open. The speed power at 10,000 feet, with pack off, was flown at a constant cowl flap setting of 2.5 inches open and oil shutters set to 30 degrees open. The data obtained from the speed versus power tests at 10,000 feet, corrected to standard atmospheric conditions and to a gross weight of 62,700 pounds, pack on, and 54,000 pounds, pack off, are plotted in Figures 4 and 5, Appendix I. The data obtained from the speed versus power tests at 18,000 feet, corrected to standard atmospheric conditions, are presented in the following table:

CONFIGURATION	Weicht LBS	MAXIMUM BHP	v _t Knots	COWL FLAPS INCHES OPEN	OIL SHUTTERS DEG. OPEN
Pack On	62,000	2260	218	2°5	30
Pack Off	53,700	2260	232	1.0	30

Fuel flows were obtained at 10,000 feet only and are presented in the form of brake specific fuel consumption and nautical air miles per pound curves as shown in Figures 6 and 7, Appendix I.

b. The combat range of the XC-120 airplanes, as calculated below. exceeds the manufacturer's estimated range. The following method was used to determine the combat range:

(1)	Take-off gross weight	64,000 pounds
(2)	Total fuel at standard weight of 6 lbs/gal	16,788 pounds
(3)	5% fuel reserve	840 pounds
(4)	Fuel for ground operations	600 pounds

(5) Climb to 10,000 ft at NRP 800 pounds Remaining usable fuel 14,548 pounds Time to climb to 10,000 ft - 14 minutes at ave. Vt of 120 knots. Distance flown 30 nautical miles.

(6) Cruise at 10,000 ft until remaining fuel. 14,548 pounds has been consumed. Cowl flaps 2.0 inches open, ave. conditions for

item No. 6. V, 157 knots, NAMPP 0.1346, weight 55,300 lbs.

Distance flown

1950 nautical miles

15,348 pounds

Total distance flown

Remaining usable fuel

1980 nautical miles

NOTE: This does not allow for the possibility of trapped fuel or for let down and landing.

10. Air speed Calibration:

The XC-120 airplane was paced, both with pack on and off, by a Flight Test Division F-51 pacer. The standard air-speed system was approximately 35 mph in error; however, the Fairchild Aircraft Company has plans for installing a new air speed system. For this reason only the swivel system was calibrated. The curve is shown in Figure 12, Appendix I.

11. Cooling:

Cooling data were taken throughout the climb to service ceiling and during various speed power runs with pack off. Ground cooling was conducted when the air was calm. Only 11 cylinder heads were instrumented by Fairchild Aircraft Corporation for this test and the data are shown in Figures 9, 10, and 11, Appendix I. Cylinder head B-1 was connected to the temperature indicator on the pilot's instrument panel; however, during flight, cylinder B-2 was found to have the hottest head.

12. Stalling characteristics:

a. Straight ahead and accelerated stalls, pack on and off, were made in the cruise, glide, power approach, and landing configuration. Power-on

stalls were undesirable in that lateral control, without exception, was lost before longitudinal control was depleted. Power off stalls were satisfactory, with the exception that very little stall warning was noticed.

- b. Power on stalls were more pronounced in that the loss of lateral control occurred before full up elevator or stall was obtained. The degree of lateral control loss and the rapidity with which the loss occurred seemed to be proportional to the amount of power on the engines at the time of lateral control loss. With loss of alleron effectiveness, the aircraft would roll predominately to the left. The roll was not abrupt or violent and could be controlled by dropping the nose until air speed sufficient for aileron effectiveness was obtained.
- c. In conjunction with the power-on stalls, there was a pronounced heavy nibbling and snatch of the ailerons preceding loss of aileron control. This increased in amplitude also in proportion to the increase in power. With rated or military power, if the wheel was allowed to jerk into a full up or down aileron position, an aileron lock would result. The aileron lock was pronounced and necessitated the pilot using both hands on the wheel to recover. This condition was not experienced during the power-off stalls and seemed to be precipitated entirely by change in air flow over the wing resulting from various power settings. Use of flaps or cowl flaps have little or not contribution to the aileron lock. During a NRP stall, clean configuration, the angle of attack was very high and aileron snatch occurred at an IAS of 64 knots (74 mph) followed by aileron lock at 62 knots (72 mph). Insufficient rudder to keep the ball centered was encountered in all power-on stalls (NRP) just before the stall.
- d. Power off stalls have little prestall varning. Two miles above actual stall, alleron nibble and slight buffet occurs. Addition of flaps down aggravates the buffet, giving slightly more stall warning. At the best, stall warning appears only about 4 mph above stall. Recovery from power-off stall may be made by lowering the nose slightly to gain air speed.

13. Control Friction:

Static control friction tests were conducted on the elevator, rudder, and alleren systems, during no-wind conditions, and found to be considerably higher than the allowable limit of 8 pounds for elevator, 15 pounds for rudder, and 6 pounds for allerens, as per USAF Specification 1815-B. Plots showing control deflection versus force are shown in Figures 13 to 15, Appendix I.

74. Dynamic Stability:

a. Longitudinal

The dynamic longitudinal stability characteristics were good. Tests were flown at a mid CG. Positive (2.0) and negative (0.0) g's were applied to the aircraft in the cruise configuration by rapid deflection of the elevator. Release of the controls on both tests resulted in a damping of oscillation within limits.

b. Lateral

This test, stick free, was conducted by yawing the aircraft 5° to the left or right in a wings level position. When the controls were .

suddenly released the rudder controls would return to neutral but the aileron controls remained in a fixed position because of the high friction force and resulted in the airplane rolling. The above test was repeated, except that the ailerons and rudders were returned manually to neutral after the 5° yaw to check control fixed characteristics. Results were somewhat more desirable indicating satisfactory stability in the control fixed configuration. Plots of stick fixed configurations are presented in Figures 50 and 51. Appendix I.

15. Longitudinal Stability:

a. Static

- (1) The longitudinal stability is very similar to the C-119B airplane in that it is very difficult to obtain reliable data because of the high static friction forces and lag of the spring tab. Tests were flown in the cruise, power approach, and landing configuration, pack on and off. The control forces for cruise and power approach configurations are, with minor exceptions, within the static friction band. Cruise and power approach configurations, stick fixed, pack on and off, do not meet Specification 1815-B. in that the most forward stick-fixed neutral point shall be at least 5% of the mean aerodynamic chord aft of the most rearward center-of-gravity position. The stick-fixed neutral points for cruise configuration, pack on and off, are approximately 30% M.A.C. The stick-fixed neutral points for power approach configuration, pack on, varied between 20.8 to 28.6% M.A.C., and pack off, 24.6 to 27.6% M.A.C. throughout the allowable speed range.
- (2) The landing configuration, pack off, conforms with Specification 1815 B, in that the stick fixed neutral points are aft of 35% M.A.C. Qualitative data only were obtained with pack on in the landing configuration. The impression was given that in this configuration the airplane behaved essentially the same as with pack off. Plots showing the static longitudinal characteristics are presented in Figures 16 through 35, Appendix I.

b. Maneuvering Characteristics

Stick force per "g" in the cruise configuration, pack on and off, are within limits as specified by 1815-B; however, the control forces for power approach and landing configurations exceed the limits specified by 1815-B, but are not considered objectionably high. There was no tendency toward a control force reversal in any configuration tosted. Maneuvering characteristic tests were conducted in the cruise configuration, pack on, and in the cruise, power approach, and landing configuration, pack off, at both forward and aft CG positions. The results of these tests are plotted in Figures 36 through 43, Appendix I.

16. Longitudinal Trim Changes:

Longitudinal trim changes were conducted on the XC-120, both with pack off and pack on, at a mid CG loading of approximately 25% M.A.C. There were no excessive forces encountered and sufficient elevator trim was available to return the elevator forces to zero for the various tests listed below:

Longitudinal Trim Changes Pack Off CG 25% ±1.5%

^{*} RPM 1800 Torque 130 pei

^{17.} Elevator Power During Take Off:

a. Elevator power is more than adequate for take-offs in the "pack on" and "off" configuration. In the "pack on" configuration, the nose wheel was lifted off at an IAS of approximately 52 knots (60 mph) at a forward CG of 20.7% MAC, and with "pack off" at a CG of 23.6% MAC, the nose wheel lift-off speed

occurred below the operating range of the air speed indicator of 43 knots (50 mph). Elevator effectiveness was sufficient to raise the nose to such an extent as to drag the pack skid or rudders with "pack on" or "off;" therefore, judicious use of elevators is recommended on performance take offs.

18. Directional Stability:

- a. Directional control characteristics were marginal. An asymmetric power condition, clean configuration, was investigated with No. 1 propeller feathered and cowl flaps closed and military power (60.5°, 2700 rpm) on the No. 2 engine. It was impossible to center the ball, using full rudder trim or rudder deflection, belown an IAS of 113 knots (130 mph).
- b. In the power approach configuration, (flaps and gear down) and with both engines producing normal rated power, there was insufficient rudder to maintain directional control during a stall. There was a gradual flat turn to the left with full right rudder. This condition was of insufficient magnitude to be objectionable and was not considered critical as it only occurred above the stall speed and at high power settings.
- c. When power was used as a variable different directional characteristics were obtained with gear up than with gear down. In the gear up configuration little variation in directional trim change was noted with the variation of power setting; however, in the gear down configuration, in flight, there is a noticeable directional trim change with power variation. The trim change was sufficient to merit retrimming to maintain coordinated flight, although the ruider force was of very small magnitude.
- d. In maneuvering flight, for all configurations, it was necessary to use rudders for coordinated turns.
- e. Steady sides lips were accomplished in the Power, Cruise, and Power Approach configuration, "pack on" and "off." Sides lip characteristics are considered normal throughout the range tested; however, sides lip angles were restricted because of the limited rudder travel, which was approximately 10 degrees less than the total rudder deflection for the C-II9B type sirplane. Plots of sides lips are presented in Figures 44 to 49, Appendix I.

19. Approach and Landing:

a. Longitudinal control during approach and landing was good. Little elevator trim was necessary in the approach, flare, or landing to achieve the proper landing attitude. Elevator forces were not excessive and could be easily controlled by the pilot. All landings were accomplished with power off, full flaps, and at a gross weight of approximately 64,000 pounds, "pack on", and 54,000 pounds, "pack off." Cowl flaps were closed and oil shutters set to 30 degrees. Reverse pitch propellers were used for each landing; however, maximum short field landings were not attempted because of the possibility of striking the skid or tail during touch down. Maximum braking power was not used because of the danger of blowing tires. All landings were photographed and the data plotted in Pages 27 through 31, Appendix III. The data, corrected to standard conditions, are tabulated in the following table:

Land No.	Pack	Gross Weight Pounds	Ground Roll Ft	Total Dist from 50° Obstacle Ft	TAS at 50' Knota	TAS at T.D. Knote	IAS at 50° Knots	Air Speed at T.D. Knots
1.	Off	54,500	1423	2392	97	83	1.05	81
2.	Off	54,300	1058	1771	97	78	104	87
3.	Off	700 ئېر	1192	1941	90	88	96	87
ĵ† ^	On	63,600	1233	1.969	94	90	98	90
5.	0:n	63 ₃ 500	1176	1813	96	84	98	89

20. Pack Handling Characteristics:

a. In general, the ground handling of the pack was very good; however, it is believed that a self-centering device should be added to the pack for ease of operation in joining the pack to the carrier. While the air-plane was at Wright Patterson AFB for Phase II tests, four spring-loaded switches, located at each suspension point and used for slack hoist cable operations, were replaced with three way switches (up, down, off) thus enabling one man to accomplish the entire operation of lowering or raising the pack. An unusual amount of time is consumed in lowering or raising slack hoist cables for attachment to the pack or to store in the carrier. Two-speed hoist mechanisms should be incorporated to correct this condition. The hoist motors were tested by raising the pack with approximately 12,000 pounds of ballast distributed in the pack and with no outside power source. No difficulties were experienced during this operation.

21. General:

a. Crew comfort was satisfactory with the exception of a high noise level during take off at higher power setting. A high frequency vibration of the compartment floor aft of the pilots seats, was very objectionable to the crew at various power settings. A slight aerodynamic roughness, in the form of a mild shaking of the aircraft frame, was felt in flight. This roughness was experienced with and without the pack and with all cowl flap settings. It is believed to be the result of turbulent air flow from the carrier striking the horizontal stabilizer.

- b. The following items were a source of trouble:
 - (1) Failure of the internal control locks.
 - (2) Erratic indication of the fuse lage door warning light.
 - (5) The inverter switches, etc. so placed that they were inadvertently knocked to the off position when the copilot left his seat.

- (4) The wheel-well doors hanging approximately 1-1/4 inches open in flight during the entire test program.
- (5) The left brake would grab, during taxiing operation, when normal pressure was applied to the brake pedal.
- (6) The electrical system was overloaded when feathering a propeller and retracting the landing gear simultaneously.

C. CONCLUSIONS

- 22. It is concluded that:
- a. The control friction, for all controls, is objectionably high.
- b. The single engine rate of climb, pack on clean configuration and at 64,000 pounds, is less than 100 ft per minute at 2000 ft.
 - c. Longitudinal stability does not meet Specification 1815-B.
 - d. There is insufficient lateral control at low speeds.
 - e. There is insufficient directional control at low speeds.
 - f. The control wheel interferes with the pilot's knees.
- g. The brake pedal angle in relation to the rudder stirrup is undesirable.
 - h. The shoulder harness release in unsatisfactory.
 - 1. The landing gear switch is located too far from the copilot.
 - j. The deelgn of the control looking system is very poor.
- k. The index end of the master battery and engine switch should be so marked.
- I. Care must be exercised to insure that the master battery switch is actually "on" when the switch is turned to the "on" position.
- m. The force necessary to operate the propeller circuit breakers is too light.
- n. Heavy buffeting of the elevator occurs when reversing the propellers during a landing.
- o. The oil cooler and cowl flap switches are confusing by not operating in like direction for normal operation.

- p. With the pack detached the towing equipment is too large to carry in the carrier.
- q. In attaching, or disengaging, the pack to or from the carrier, approximately half of the time required for the complete operation is consumed in lowering or stowing the hoist cables after the pack has been dropped or attached.
- r. It would be difficult to attach the pack to the carrier during blackout or gusty conditions without a centering device.
- s. Estimated performance and test results are presented in the following table:

CONDITION	ESTIMATED PACK ON	PERFORMANCE PACK OFF	TEST PER PACK ON	FORMANCE PACK OFF
Gross weight at T.O. pounds	64,000	55,000	64,000	55,000
Maximum speed at 18,000 ft. knots	211	229	218	232
Time to climb to 10,000 ft (min)	10,4	7.0	13.5	9.5
Service ceiling - 2 engine ft	23,625	27, 500	22,800	28,000
Service ceiling - 1 engine Military power - ft	4,210	13,500	None	6,800
Take-off distance over 50 ft.	2,800	2,060	2,560	2,000
Combat range at 10,000 ft. naut. mi.	1,865		1.980	

D. RECOMMENDATIONS:

- 23. It is recommended that:
- a. The control friction for all controls be reduced to meet USAF Specification 1815-B.
- b. Single engine performance, "pack on," be improved to the point that the aircraft would be militarily usable.
- c. Longitudinal stability be improved to meet military requirements.
- d. Interal control be improved at low speeds to meet military requirements.
- e. Directional control be improved at low speeds to meet military requirements.
- f. The control wheel be raised so it does not interfere with the pilot's knees.

- g. The brake pedals be installed on a plane or angle different from the rudder stirrup angle.
- h. The shoulder harness release be modified, so the release will work each time the release lever is actuated.
- i. The gear switch be relocated so as to be easily accessible to the copilot and pilot.
 - j. The internal control lock be redesigned.
- k. Guards be installed for the hydraulic brake pump, main and automatic inverter switches.
- 1. The index end of the master battery and engine switches be so marked.
- m. The master battery switch be replaced with a positive position switch.
- n. The force necessary to operate the propeller circuit breakers be increased.
- o. Elevator buffeting be decreased or eliminated during propeller reversal operation.
- p. The oil cooler switches be located near the cowl flap switches and operate in the same direction as the cowl flap switches.
- q. The towing equipment be modified so it may be conveniently stowed in the carrier when the pack is detached.
- r. A two-speed hoist mechanism be installed for ground pack operations.
- g. A self centering device be added to the pack for ease of operation in joining the pack to the carrier.

1. Data Analysis

a. Introduction:

This section briefly discusses the methods of reduction used in analyzing the test data. The following reports will be referred to in this discussion:

- No. 1 "Performance Flight Testing Methods in Use by the Flight Section", USAF Technical Report No. 5069
- No. 2 "Pressure Altitude Method of Flight Test Data Reduction", AMC Memorandum Report No. TSFTE-2060
- No. 3 "Model R-4360-20, -20W, Engine Specification", No. N-7056-C, dtd 23 September 1949
- No. 4 "A Simplified Manifold Pressure Correction", AMC Memorandum Report No. TSCEP5E-1919
- No. 5 "Army-Navy Aeronautical Specification Test Procedure for Aircraft Power Plant Installations", AN-T-62, dtd 31 October 1944

b. Take-off and Landings

Distance, time, and height data for the take-off and landing tests were obtained with the photographic equipment at Wright Field. All data were then plotted on the curves shown in Appendix III. Other data tabulated on these curves were obtained from the airplane except the wind velocity and direction which were recorded by the photoscope crew. The distances and air speeds at take-off and at an altitude of 50 feet were taken from these curves and corrected to an NACA Standard, sea-level, no-wind day by the following equations:

(1) For Take-offs

Corrected Ground Roll = Test Ground Roll $(V + V_W)/V$ 1.85 x 6 x R

V = Ground Speed at T.O. - ft/sec

V_w ≈ Component of wind down runway ≈ ft/sec headwind (+)

6 = Density ratio

R = Rate of climb at equivalent altitude
Rate of climb at sea level

Equivalent Altitude = Pressure altitude - .36 x (pressure altitude - density altitude)

Corrected air distance (point of take-off to an altitude of 50 feet) =(test air distance + V_W t) x $e^{1/2}$ x R

Where t = time from lift off to an altitude of 50 ft

Weight corrections were made by the expressions

$$S_w = S_c (W_s/W_t)^n$$

Where Sw = distance corrected for weight

Sc = distance corrected for wind, altitude, and power

W = gross weight, test and standard

n = 2.7 for ground roll 2.2 for total distance

(2) For landings the corrected ground roll = test ground roll (V + V_W)/V $^{1.85}_{\text{XC}}$ and corrected air distance = test air distance \neq (V_W t). No weight corrections have been developed for landing distances.

c. Climb

Where

(1) Climb data were reduced to the rate of climb that would have been obtained in standard air with standard horsepower at the climb speeds tested. The equation used for this reduction was:

$$R/C_{std} = \frac{dh}{dt} \times \sqrt{\frac{T_T}{T_S}} + \frac{35,000 \text{ n}}{W} \text{ (bhp}_S - bhp}_t \sqrt{T_S/T_T})$$

$$\frac{dh}{dt} = \text{test rate of climb}$$

$$T_T = \text{test free air temperature, Kelvin}$$

$$T_S = \text{standard free air temperature, Kelvin}$$

$$n = \text{propeller efficiency usually taken as .8}$$

$$W = \text{test gross weight}$$

bhps = standard brake horsepower

bhpt = test brake horsepower

Development of this method is outlined in Reference No. 2. Climb data were also corrected to a weight corresponding to a standard take-off gross weight minus the weight of the fuel used to warm-up, taxi, take-off, and climb to the test altitude. Thus, climbs were corrected to a different weight at each altitude. This correction was made by use of the equations:

APPENDIX I

Where R/CT = Test rate of climb

AW = Ws - Wt

W_S ≈ Standard gross weight

Vc = Calibrated air speed - mph

e = Airplane efficiency factor

b = Airplane wing span - ft

These equations were developed and presented on nomograms in Reference No. 1.

- (2) Standard horsepower for climb was taken as the horsepower developed in standard air with standard carburetor air temperature st the test air speed with either 50 inches of mercury manifold pressure or full throttle and full high blower. This was accomplished by the following procedure:
 - (a) Obtained standard carburetor air temperature, CATs.

$$CAT_{S} = CAT_{t_i} + T_{s_i} - T_{t_i}$$

- (b) Corrected the brake horsepower to CAT_S at test manifold pressure. BHP = BHP_t $\sqrt{\text{CAT}_T/\text{CAT}_S}$
 - (c) Obtained the MAP change owing to the CAT change at a constant blower speed from curves appearing in Reference No. $h = 100 \, {\rm km}$ simplified the equation

$$MAP_{S} = P_{A} \begin{bmatrix} T_{K_{T}} & (MAP_{T}/P_{1}).238 & J \\ T_{K_{S}} & T_{K_{S}} \end{bmatrix} + 1.$$

Where

Pi = Inlet pressure, "Hg

MAPs - Standard day manifold absolute pressure, "Hg

MAPt = Test manifold absolute pressure, "Hg

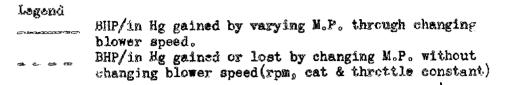

TKm Test inlet air temperature, o Kelvin

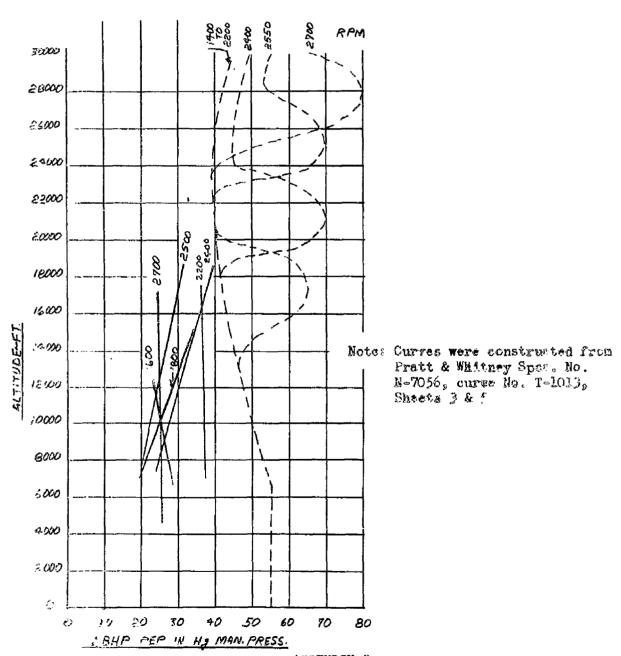

TKs = Standard inlet air temperature, o Kelvin

(d) Corrected the BHP for this change in MAP from figure / developed from engine manufacturer's power curves, Reference No. 3, assuming a constant blower speed. The test point was at this point corrected to standard conditions but if below the full throttle high blower point, may not have been on the desired 50 "Hg of manifold pressure.

(e) Placed the MAP on the schedule and corrected the horsepower for this change in MAP from figure 1 assuming a change in blower speed if in the slip region of the clutch and constant blower speed if not. These two corrections are shown on the following page in graph forms

Fig. No. 1
Power Correction
Chart
R-4360-20W Engine

d. Level Flight

(1) Speed versus horsepower calibrations were obtained at various altitudes by stabilizing the air speed in level flight with various power settings. The test data were corrected to standard day atmospheric conditions by adjusting the horsepower to that necessary to maintain the test air speed with the formula:

 $HP_{std} = HP_{t} \sqrt{T_{s}/T_{t}}$

Where HPs = horsepower required to fly the test air speed on a standard day

HPt = horsepower delivered on the test day

T = free air temperature, Kelvin sub s = standard and sub t = test

An induced drag correction for weight was applied by the formula:

$$4BHP = \frac{.3318 (W_s^2 - W_t^2)}{n e b^2 = V}$$

Where n = .83 = propeller efficiency

e = .77 = airplane efficiency

b = wing span, ft

= density ratio

V = true air speed, mph

This formula is solved graphically in Reference No. 1

(2) All speed versus power data were also reduced to a Piw versus Viw curve by the equations:

Viw =
$$V_e/(W_s/W_t)^{1/2}$$

Piw = P = $1/2(W_s/W_t)^{3/2}$
Niw = N = $1/2(W_s/W_t)^{1/2}$

Where Viw = weight reduced indicated air speed

 V_e = equivalent air speed = V_c = ΛV_c

Piw = weight reduced indicated horsepower

P = test horsepower

Niw = weight reduced indicated rpm

N ≈ test rpm

W = gross weight, sub s = standard and sub t : test.

≤ = density ratio

e. Cooling

Engine cooling data were recorded during some of the level flight tests and during one of the climbs to service ceiling. A Brown automatic temperature recorder was employed for obtaining the temperatures. Cooling corrections were made as follows:

(1) Air Force Hot Day

$$T_c = T_t + \left[(T_{std} - T_T) + 23^{\circ} \right] K$$

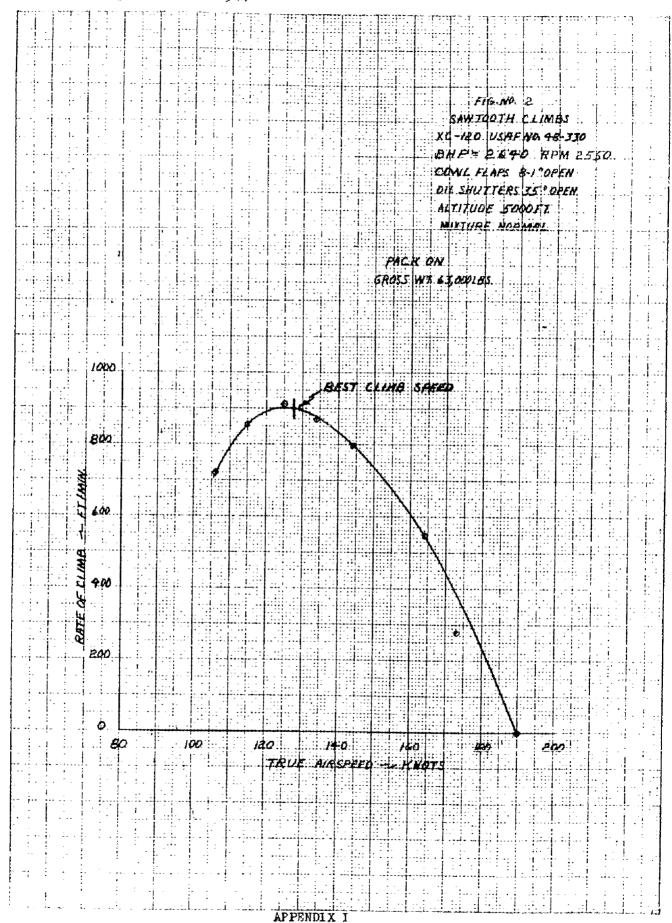

Where

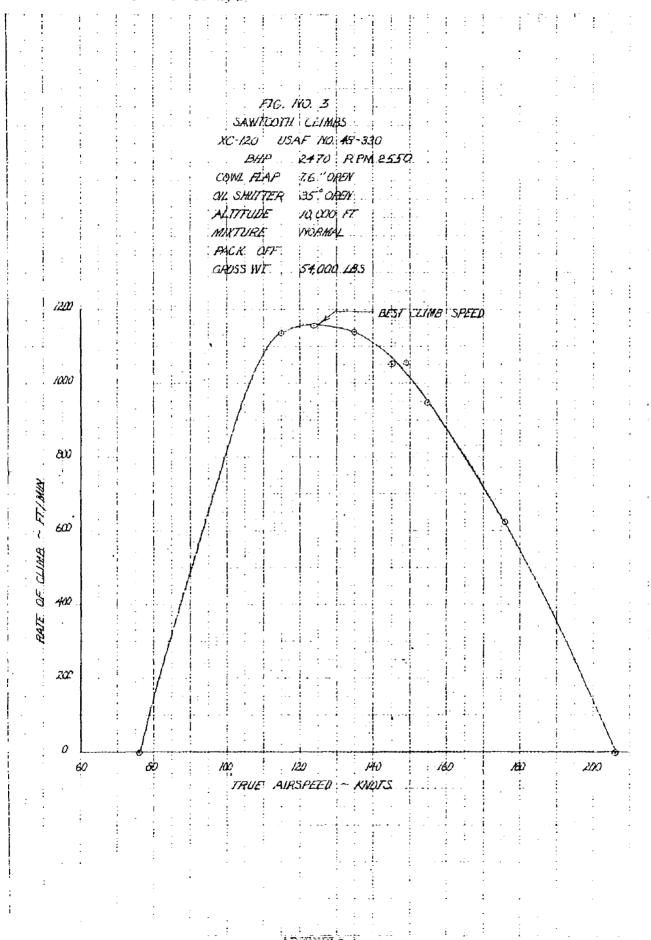

To = corrected to Air Force hot day of hilvin

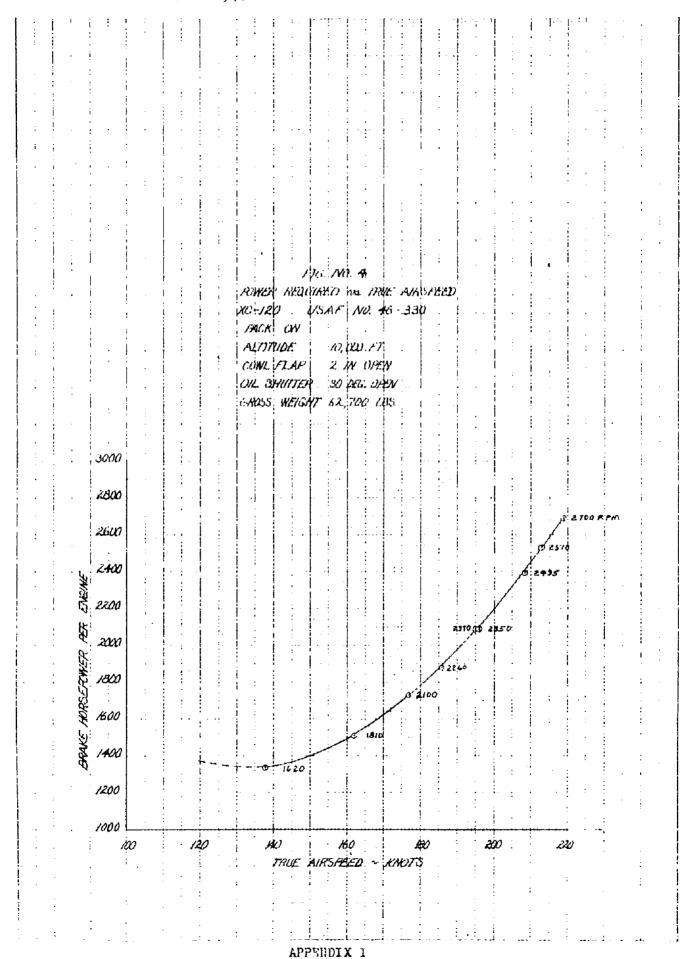

Tt = test temperature

 T_{std} = standard temperature at altitude

k = correction factor defined in Specification AN-T-62

L. Instrumentation

Installation of test equipment was made at the factory. After delibered of the airplane, to Wright-Patterson Air Force Base, Area B, the tollowless changes were made:

- a. Photobax mirror door was modified to allow observer to within instruments at the same time pictures were taken.
 - b. Additional stability instruments were added to the pilot's pane...
 - c. Servo force indicators and amplifuers were modernized.
 - d. New type FW 8 camera replaced auto-rewind type.
- e. One each AN 5525-1 type resistance bulb was installed in Call carburetor our scoop to measure carburetor air temperature.
- f. C-10 type temperature indicators were installed in the photobox to indicate carbureror air temperature.
 - g. Tarque system was modified.
- h. Original engine thermocouple installation called for cylinder head and ylinder base temperatures on the right engine; however, after Fairchild Aircraft Company had experienced a failure of the right engine. It was decided to instrument only certain cylinder heads of the new engine. This decision was based on tests conducted on C-119B airplane.
- i. Fuel flows were recorded from a Revere Blue Top totalizer installed on the right engine, however, difficulties were experiented with the py-pass system, and this was later modified by replacing the Log-pound by pass spring with a 5-pound by-pass spring.
- The standard air speed system was approximately 35 mph in error; therefore, the swivel air speed system was used throughout the best program. An F-51 pacer airplace was used to calibrate the swivel system, with both the pack on and pack off of the XC-120 sirplane.
